Assignment 3 reflections

The target model, GPT 4.1 is advanced enough to perform simple math adequately. As counter to my intuition as this is, the explanation is simple. At this level, a lot of basic math questions have been built into the weight of the model, and it can correctly predict a math question and answer. The catch is that prediction is not calculation, and any complex or novel patterns can't be cleared. What a calculator can do in under a second, this model will fail and spend way more energy for. These days, advanced models rely on the harness to identify calculations that are then delegated to a python script builder (although Rust is more popular right now), or in some cases, an expert from an MoE model with better associations and classification options for the situation. I would still never trust this system with math, but it is funny to see that it will not fully fail at the task.
